

The time of COVID-19: Clinical approaches and research within 2 months of arriving in Mexico

Gisela Vázquez-Flores and Marie Catherine Boll*

Clinical Research Laboratory, Ataxias, Chorreas and Other Rare Diseases, Instituto Nacional de Neurología y Neurocirugía "Manuel Velasco Suárez", Mexico City, Mexico

Abstract

By the end of 2019, a peculiar epidemic appeared in China; it was of the flu-type and revealed a lethal zoonosis caused by a beta coronavirus. In this study, we review the history of this new pandemic starting from its origin; we describe how COVID-19 spread its symptoms, especially the neurological ones, and the investigations currently underway.

Key words: COVID-19. SARS-CoV-2. Symptoms. Diagnostic tests. Clinical trials.

Tiempos de COVID-19: aproximaciones clínicas e investigaciones en dos meses desde su llegada en México

Resumen

A finales del 2019 surgió en China una peculiar epidemia de tipo gripe, que reveló ser una zoonosis letal causada por un betacoronavirus. Revisamos en este artículo la historia de la ahora pandemia desde su origen, describimos los síntomas, especialmente los neurológicos, y las investigaciones actualmente en curso.

Palabras claves: COVID-19. SARS-CoV-2. Síntomas. Pruebas diagnósticas. Ensayos clínicos.

Introduction

By the end of 2019 in Wuhan, pneumonia of unknown etiology emerged. A new kind of betacoronavirus was identified when only two beta-coronaviruses were associated with respiratory syndromes in humans: Middle East Respiratory Syndrome Coronavirus (MERS-CoV) and Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV). The new virus was called SARS-CoV-2 by the International Committee of Virus Taxonomy. However, significant differences were found in transmission,

pathogenesis, and clinical presentation between the new virus and the other SARS-CoV.

The surge of a new strain

The attendance to the Chinese Spring Festival implied the rapid mobilization of infected persons. The first five studied patients presented high fever and dry cough and four developed respiratory distress. Subsequently, a study in 137 patients concluded that middle-aged and

elderly subjects with comorbidities have a poorer prognosis¹. Next, angiotensin-converting enzyme-2 (ACE2) was identified as a SARS-CoV-2 receptor. ACE2 expression has been found in kidneys, intestines, gallbladder, nervous system, and placenta. In lungs, the target organ, it was much lower. On the other hand, ACE2 was strongly expressed in proximal tubules. Thirty-six of 536 patients presented acute renal failure 20 days after the onset, even though baseline creatinine levels were normal².

Clinical manifestations

Mainly respiratory, a dry cough accompanied by fever and mild constitutional symptoms is present in the first phase of the viral response (stage I). Then, shortness of breath without or with hypoxia corresponds to the moderate phase or pulmonary involvement, when patients develop viral pneumonia and when an abnormal chest computed tomography (CT) scan can be useful for rapid diagnosis to optimize management. A 3-stage classification and establishment of a standardized nomenclature were recently proposed for reporting the disease and orienting therapeutic interventions. Indeed, in stage II, the host's inflammatory response increases until it reaches hyper inflammation in stage III with acute respiratory distress syndrome, systemic inflammatory response syndrome, and cardiac failure accompanied by the peak of pro-inflammatory cytokines, troponin, and NT-proBNP elevation. At this time, corticoid or immunomodulatory treatments can be beneficial³.

SARS-CoV-2 can affect other systems and cause abdominal pain, diarrhea, vomit, anorexia, acute renal failure, and a series of symptoms considered as neurological: dizziness, headache, consciousness impairment, acute cerebrovascular disease, ataxia, seizures, peripheral nervous system damage consisting of oculomotor palsy, the frequent anosmia/ageusia, other neuropathies, and also myalgias. In the mild phase of coronavirus disease (COVID)-19, an interplay between pro-inflammatory cytokines and chemokine release, increased endothelial damage, and potential sepsis induces coagulopathy development. It is known that the cytokine storm, macrophage activation, leukocyte adhesion molecule overexpression, together with the marked expression of ACE2 in the vascular endothelium, makes it a clear target of the disease. Therefore, COVID-patients are at risk of thrombogenesis due to both biochemical hypercoagulable state and direct vascular damage. A major neurological manifestation is

ischemic stroke involving large vessels, often in multiple vascular territories and associated with elevated D-dimer, ferritin, anticardiolipin, and phospholipid antibodies⁴.

The mechanism of neuroinvasion has not been elucidated, though it could be due to a direct infection by SARS-CoV-2 as part of acute toxic encephalitis or by axonal transport through the olfactory system. The presence of viral particles in olfactory epithelium has been related to anosmia, an initial symptom that can persist until the moderate phase. The most severe phase of hyper inflammation threatens the integrity of the blood-brain barrier. Toll-like receptors activation in microglia and astrocytes may explain the association with encephalitis, encephalomyelitis, acute necrotizing encephalopathy, meningitis, transverse myelitis, and acute cerebellar inflammation. Furthermore, post-infectious and immune mediated neurological complications are described, including Guillain-Barré syndrome and its variants that usually appear in the moderate and severe phases and some rare cases of acute disseminated encephalomyelitis-like encephalomyelitis⁴.

SARS-CoV-2 was isolated in cerebrospinal fluid from two patients with meningoencephalitis but not in nasal swabbing. One of them underwent severe disorder of consciousness; the other presented seizures. Previously, pediatric cases with Kawasaki-type vasculitis have been reported in New York. The first case, a 6-month infant had fever, tachycardia, tachypnea, irritability, conjunctivitis, and cracked lips. On day 5, the infant exhibited maculopapular exanthema and edema in limbs. Diagnosed with Kawasaki disease (KD) and immunoglobulin therapy was initiated. Eight pediatric English patients with KD showed shock signs; one died after ischemic strokes, and seven exhibited right heart ventricular failure. These latter improved after Immunoglobulin therapy and antibiotic treatment⁵.

The arrival of the pandemic in Mexico

The first case of COVID-19 in Mexico, a 35-year-old male subject returning from Bergamo, Italy, was confirmed on February 28, while an increase in the number of cases in Western Europe was evident. Subsequently, preventive measures were taken such as avoiding physical contact and massive events (Table 1). On March 24, 405 cases were confirmed and phase 2 implemented with homeschooling and home-office during the quarantine (Fig. 1). At the beginning of April, a

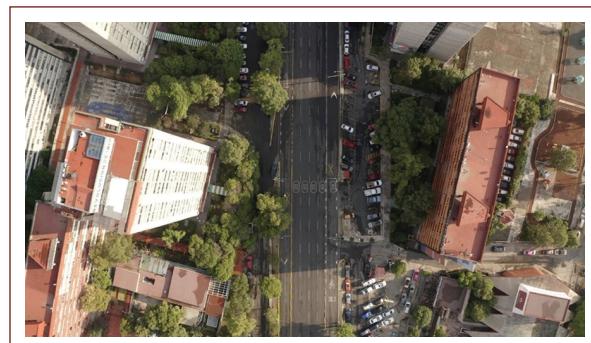

Figure 1. Empty avenue in Mexico City during April 2020 contingency. Photo bequeathed by DRONERO.MX.

sharp rise in the contagion curve took place, but it was until April 21 that phase 3 of the pandemic was declared so as 857 deaths (Fig. 2).

Current research (Table 2)

After sequencing genetic material of SARS-CoV-2 (RNA), the first RT-polymerase chain reaction (PCR) diagnostic tests were developed. It has a sensitivity range of 56%-83% and specificity of 95%. The presence of the virus in aerosols and surfaces was then studied. SARS-CoV-2 remains in aerosols for 3 h and 8 h in copper; it is not found in carton after 24 h, but it is more stable on stainless steel for 48 h and on plastic with a viability of 72 h⁶. After PCR diagnostic test, serological tests were settled. A French laboratory developed a fast one called NG-Test IgG-IgM COVID-19 All-in-One that detects and differentiates antibodies against SARS-CoV-2 in blood. This test was carried out in 101 patients with COVID-19 and rendered a positive result in 95% on day 15⁷.

In Mexico, the laboratory Lansbiodyt at the UNAM University is developing a biomarker detecting magnetic pearls that bind to the RNA of SARS-CoV-2 virus and send a fluorescent signal measured with a versatile biomolecule sensor. This method can detect a small viral load and is currently under validation.

Research on the control of hypoxic complications led to a clinical study in France on *Arenicola marina*, given that hemoglobin from this marine worm can transport 40 times more oxygen than the human one and is compatible with all human blood groups. The company Hemarina intends to use this hemoglobin for treating COVID-19. The study began in 10 patients with severe COVID-19 and on ventilators, but on April 19, the trial was stopped by the French Security

Agency of Medicaments. In this same country, a study using hydroxychloroquine administered with azithromycin was carried out in 36 COVID-subjects when admitted to hospital. It was an open clinical trial. Main criticisms on this research are the risk of QT lengthening in the electrocardiogram and the low level of evidence, though the outcome was rather promising⁸.

Another therapeutic possibility is ivermectin, an anti-parasitic with potent antiviral activity toward HIV and dengue. In a study in Vero/hSLAM cells infected with SARS-CoV-2, a 5 mM of ivermectin treatment showed after 24 h, that viral RNA was reduced by 93% in the supernatant. At 72 h, no remnant could be detected⁹. However, the dose utilized in Vero cells is 35 times higher than the Cmax allowed in human plasma after oral administration of the approved dose of ivermectin. At present, there is still no evidence of the efficacy of this drug in treating patients with COVID-19.

In the UK, RECOVERY, a randomized controlled trial, announced preliminary results in 2104 patients that showed that dexamethasone reduced significantly the 28-day mortality rate with the greatest benefit among those patients requiring mechanical ventilation but also in patients who only received oxygen therapy.

Among other therapeutic options, mesenchymal stem cells are expected to control the exacerbated immune response exhibited by patients. After cell transplantation, ten patients improved significantly in 2-4 days, PCR levels were low, also inflammatory cytokines diminished and chest CT showed a reduction in lung infiltration on the 9th day¹⁰. Meanwhile, an epidemiologic study in 175 countries shows a significant reduction in morbidity and mortality from COVID-19 in countries with BCG vaccine as part of their individual policy¹³.

Table 1. Control and prevention interventions of COVID-19 in different scenarios¹¹

| Scenarios | 1. Viral import Dozens of cases | 2.-Community dispersion Hundreds of cases | 3.- Epidemic Thousands of cases |
|--|--------------------------------------|--|--|
| Greeting between people | No restriction | No kiss, no hug | No kiss, no hug |
| Closed public spaces (theaters, stadiums, cinemas, etc.) | Not necessary | Suspension of events before outbreaks | Suspension of events before outbreaks |
| Open public spaces (malls, parks, beaches) | Not necessary | Suspension of events before outbreaks | Suspension of events before outbreaks |
| Schools, high schools and universities | Dissemination of preventive messages | School filter | Suspension of classes in schools during active outbreak |
| Workplaces | Dissemination of preventive messages | Sanitary filter | Suspension of work activities in workplaces during active outbreak |

Table 2. Relevant ongoing research in March and April 2020

| | Type of study | Sample size | References |
|---|---|---|-----------------------------------|
| NG-Test IgM-IgG COVID All-in-One detects specific antibodies anti-SARS-CoV-2 of IgG and IgM types in blood, serum, or plasma, producing results in 15 min. Positive outcome from day of infection to day 15 (p = 0.001) | Development of serologic test | 101 patients | Dortet et al. 2020 ⁷ |
| Lansbiodyt Laboratory at the University of Mexico (UNAM) develops a biomarker that binds to SARS-CoV-2 virus and emits a quantifiable fluorescent signal at low cost. Project UNAM-INDRE-001 | Diagnostic test | 40 patients. On hold until financing is available | UNAM 2020 ¹² |
| Hydroxychloroquine and azithromycin as treatment for COVID-19 patients. It reduces viral load in PCR assay in nasopharyngeal swabbing (p < 0.001) | Non-randomized clinical trial | 36 patients | Gautret et al. 2020 ⁸ |
| Countries with BCG vaccine as part of their individual policy show reduction in morbidity and mortality in patients with COVID-19 (p = 0.0001, and p = 0.05, respectively) | Epidemiologic study in cases and controls | 175 countries | Ozdemir et al. 2020 ¹³ |
| Antiparasitic Ivermectin reduces the viral load in Vero cells infected with SARS-CoV-2 assayed by RT-PCR | In vitro study | 10 simulations | Caly et al. 2020 ⁹ |
| Transplant of mesenchymal stem cells ACE2 reduces inflammation in patients with pneumonia caused by COVID-19 (p < 0.05) | Clinical trial | 10 patients | Leng et al. 2020 ¹⁰ |
| Patients administered Remdesivir show a 2-point clinical improvement on a 1-6 scale after 10 days, with viral load reduction | Randomized clinical trial (pilot study) | 237 patients | Wang et al. 2020 ¹⁴ |
| Patients treated with 200 mL of plasma from convalescent patients of COVID-19 show significant clinical, biochemical, and radiologic improvement | Open trial | 10 patients | Duan et al. 2020 ¹⁵ |
| IgG and IgM antibodies target receptor S binding dominion (S-RBD) of SARS-CoV-2 and select it as humoral immunity target to become the aim for the development of vaccines | Pre-clinical phase and Phase 1 | 12 patients | Ni et al. 2020 ¹⁶ |

Another study in 10 severely ill COVID-19 patients explored the administration of plasma from recovered patients. This procedure significantly improved symptomatology and viral load¹⁵.

Vaccine research has been undertaken in different countries, reaching relatively advanced stages such as

the recently published clinical trial with AD5-nCOV. One hundred eight healthy individuals received low (0.5 mL), medium (1.0 mL), or high (1.5 mL) doses of Ad5 vectored COVID-19 vaccine; 83% in low and medium doses and 75% in high doses reported mild or moderate adverse reactions consisting of pain in the injection site,

fever, fatigue, headache, and myalgia. ELISA and neutralizing antibodies increased significantly from day 14 and specific T-cell response was rapidly reached¹⁷.

In Mexico, ten patients with COVID-19 were participating in a clinical study to test the efficacy of remdesivir. On May 12, 9 out of 10 patients had been discharged and the antiviral clearly showed significant shortening in the course of the disease.

Conclusion

Similarly to COVID-19, research to fight the mortal agent will take quite a while. This pandemic has shown that we are facing a virus capable of disrupting global economy in a few months and draws attention to human fragility as was experienced in the big epidemics of antiquity, Middle ages, or the more recent Spanish Flu. Within a vicious circle, the economic and health repercussions slow down research progress at the risk of having to live the effects of SARS-CoV-2 for a long time. The whole world awaits the teachings of mass testing and the arrival of a vaccine. Furthermore, neurological manifestations that could be classified as early and systemic, neuroinvasion, and post-infectious immune-mediated have very diverse presentations and mechanisms that remain to be clarified.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Conflicts of interest

The authors declare no conflicts of interest.

Ethical disclosures

Protection of human and animal subjects. The authors declare that no experiments were performed on humans or animals for this study.

Confidentiality of data. The authors declare that they have followed the protocols of their work center on the publication of patient data.

Right to privacy and informed consent. The authors declare that no patient data appear in this article.
