

## *An interpretation of the behavior of the mark up in the Brazilian industry*

CARMEM APARECIDA FEIJÓ  
LUIZ FERNANDO CERQUEIRA\*

### **INTRODUCTION**

The Brazilian economy experienced significant changes during the 1990s. Economic and financial deregulation, price stabilization and privatizations configured a new economic scenario, shaping new attitudes and strategies of agents. In spite of these changes, economic performance was poor during the decade. Economic growth was marked by short periods of growth followed by deceleration periods. The gross capital formation (or investment) rate, a key variable to explain the dynamism of the economy, was around 17.0%, whereas current estimates by governmental officials point to an investment level of around 25.0% as a requirement for a 5.0% sustained annual growth rate.

Despite slow growth, the 1990s saw the recovery of industrial productivity, which had been stagnated since the 1980s. This result can be largely attributed to the external deregulation and exchange rate valuation after the stabilization

plan in 1994. In this sense, the recovery of industrial productivity can be understood as the result of the change of the relative price vector of productive resources, contributing to an increase in production efficiency. Yet, to what extent did this supply shock affect the decision process regarding price formation by private firms? The motivation for the article is associated to these aspects.

The microeconomic literature points out that the increase in production efficiency as a result of more flexible commercial relations should result in, at least, two positive effects on the economy.<sup>1</sup> On the one hand, a greater exposure to foreign competition should encourage firms to improve their product quality and productivity by employing more efficient inputs. Thus, an increase in economic growth rates should be expected, encouraged by the acceleration in incorporating technological change. As has been mentioned, economic growth rates were low in the 1990s. On the other hand, the reduction in tariff and non-tariff barriers should imply broadening the market for more firms, increasing competition and contributing to a reduction in profit margins. As will be seen in this article, reduction in profit margins was not observed either.<sup>2</sup>

Considering the macroeconomic scenario in the 1990s, the objective of this paper is to investigate the influence of the new economic environment on the industrial firms pricing decision. In this sense, this text discusses causal links and investigates empirically variables that can be identified as

---

<sup>1</sup> Ferreira and Guillén (2004) present two other effects; we highlighted only these two.

<sup>2</sup> As will be presented in this article, our results about the behavior of mark up of industrial firms in the 1990s showed that the mark ups changed and, in general, increased (table A1). These results contrast with those found by Ferreira and Guillén (*op. cit.*), which observed that the mark ups changed little. The authors, when presenting the results of their econometric estimates about the effect of economic deregulation on the Brazilian productivity and production framework, concluded that: "The channel to this increase in productivity is not, apparently, the increase in competition, since there is no statistical evidence of mark up reduction. This is perhaps the most surprising result in the article, the fact that the mark up does not change significantly after commercial deregulation." (p. 527). Moreira and Correa (1997: 85), departing from a different data base and analyzing the impact of commercial openness in Brazilian industry from 1990-1995, found a different result for mark up behavior. They observed significant decrease in profit margins in industries producing tradables, but increase in Beverage, Pharmaceuticals, Cement and Paper and Rubber.

having influence in price formation in the 1990s, through the determination of the mark up of industrial firms. Price formation is a key variable to explain the production and accumulation behavior of the firm, because it largely determines the generation of firm's profits. Also, pricing strategies of firms are fundamental to the understanding how monetary policy affects the real side of the economy. In spite of the relevance of the subject, empirical studies about mark up determination in Brazil in recent times are scarce and not conclusive (see footnote 2). In this context the contribution of this paper is to add new arguments to explain industrial mark up behavior in the nineties.

This paper works with the assumption that prices, in a large portion of the economy, are fixed through the application of a mark up over production costs. The main reference here is the classical empirical study of Hall and Hitch (1939). Thus, the key variable that firms administrate is the mark up –not the price itself–. But, as pointed out by Sawyer (1981: 139) the Hall and Hitch approach to price determination does not state the forces determining the mark up. In this paper we will assume that the decision about the mark up depends on the firm's perception in relation to the behavior of the market for its product and on the macroeconomic environment, given a growth strategy chosen to be followed over time. These hypotheses allow for the establishment of an interesting relation between microeconomic and macroeconomic variables in the firm's decision process, as well as an important interaction between short term and long term decisions (Feijó 2002).<sup>3</sup>

This text develops in the following way, besides this introduction. In section two we briefly present theoretically how the price formation process takes place in the context of an oligopolistic firm deciding under uncertainty. In section three we discuss how changes in the macroeconomic scenario of the Brazilian economy in the 1990s affected the industrial firm's behavior regarding the determination of the mark up. In section four we

---

<sup>3</sup> For references of empirical surveys on pricing, see, for example, Sawyer (1981, chapter 9) and Lee (1995, Appendix A, B and C).

present the econometric results of the model for the determination of the industrial mark up in industrial Brazilian firms in the 1990s, and the last section summarizes our conclusions.

### **AN OVERVIEW OF PRICE DETERMINATION IN THE POST KEYNESIAN LITERATURE**

The Post Keynesian literature attributes particular interest in the mark up determination as it considers that production, price and investment decisions are linked to mark up decision.<sup>4</sup> In this literature, mark up behavior is the result of the interaction of a complex set of economic forces.

Under the assumption that decisions are made under uncertainty, firms cannot fully evaluate the consequences of their actions, and therefore determine for sure the price that maximizes their profits. So, the mark up becomes the strategic variable firms manipulate in search of their maximization targets.<sup>5</sup> Post Keynesian authors advocate that price formation process reflects how diversified firms build their growth strategies according to how they perceive the future behavior of demand, costs, and competition.<sup>6</sup> In this sense we recall Penrose's (1959) observation, that it is subjective judgment, rather than objective fact that is considered in firm's decision making process.

According to the Kaleckian tradition, the supply price in oligopolized markets reflects the firm cost structure and market power. Such power is

---

<sup>4</sup> For example, Eichner (1973, 1976, 1985), Harcourt and Kenyon (1976); Davidson (1978), Kenyon (1979); Shapiro (1981); Ong (1981), Feijó (1993), Arestis and Milberg (1993), Lee (1998), Downward (2000), Shapiro and Sawyer (2003) among others.

<sup>5</sup> Davidson (1978), among many others, suggests that prices are formed by means of a mark up rule over costs given a production level considered as being standard.

<sup>6</sup> An interesting remark about Post Keynesian price theory is that it deals with the process of price setting according to the firm's perception of the opportunities to grow, rather than with limit situations. In this sense the level of the mark up will depend on the circumstances as perceived by the firm. A limit situation such as the one where the firm sets its mark up in a level fully compatible with its monopoly power, would not be a reasonable choice for a firm deciding under uncertainty, as in that case the firm would have no room for maneuver to increase its investment, if the level of its internal funds (retained earnings) is not enough to cover additional expenditure.

associated with two factors: the capability of passing on any direct cost pressure to prices, regardless of the competitors pricing policy and the improvement of a firm's relative position in its industry, even in the absence of changes of its cost structure. Consequently, the price-direct cost ratio –a firm's mark up– reveals its discretionary power in fixing price, and it is an indicator of the degree of monopoly.<sup>7</sup>

Besides price determination depending on production costs and demand behavior, in the Post Keynesian literature it also depends on the internal fund requirements to realize the firm's investment plans.

Given these behavioral hypotheses, Kenyon (1979:39) proposes a sequence of arguments to explain the determination of the mark up by an oligopolistic firm. First, the firm decides about the future investment plans based on the relation between the observed capacity utilization rate and some desired rate –this desired rate being such that the firm will be capable of meeting a sudden increase in demand for its product; after that, the firm chooses the mark up that will allow it to retain the profits required to fulfill its obligations and meet its strategic objectives–. The firm then chooses the mark up that will provide the expected profit level. The firm will maintain this price as long as demand conditions indicate that the productive capacity is adequate, and as long as production costs do not deviate from their normal level.

As Shapiro and Sawyer (2003) pointed out, although prices depend on costs, there is no automatic transmission mechanism from costs to prices, that is, prices depend on the mark up (a strategic decision), as well as on costs. When costs change, prices do not necessarily change, the mark up over the costs may change instead.<sup>8</sup> In the same way, when demand changes, firms with oligopoly power will decide to change prices according to their

---

<sup>7</sup> According to Kalecki (1971) the firm's mark up is determined by the degree of competition between firms in an industry  $(p_i - u_i)/u_i = f(p^*/p_i)$ , where  $p^*$  is the weighted average price in an industry,  $u$  is the direct cost, and  $i$  represents the firm's subscription.

<sup>8</sup> As presented by Sylos-Labini (1969), the price equation can be written as:  $p = v + qv$ , where  $p$  is the unit price,  $v$  represents direct operational costs, and  $qv$  represents the overhead (over a standard production volume) and an acceptable profit margin per product unit.

strategy of capital accumulation in the long run. Again, there will be no automatic mechanism linking price changes due to changes in demand.

Assuming that rivalry between firms that constitute an industry is enough to ensure that no investment opportunity is wasted, the strategic variable in the study on mark up behavior is the level of expenses with investment by the firms. Investment decision will be driven by rivalry among firms, market growth expectations and the desire to maintain or broaden market share.

Minsky (1986) contributed to make deeper the understanding of the interaction process between the microeconomic and macroeconomic spheres by showing how mark up decisions are also influenced by the need to generate cash flow to pay for financial commitments taken on.<sup>9</sup> In this context, the process of price formation and mark up determination by firms should be aimed at generating enough profits (or cash flows) to provide resources for the investment financing process. Firms should, therefore, include in their supply prices an amount that, besides exceeding their costs, should also generate enough funds to sustain or value their capital assets. Prices, in this sense, must be related to: *a*) the need to generate funds that will make the capital accumulation process possible, *b*) make payments of debts feasible, *c*) induce and partly finance investments and *d*) make the acceptance of new financial obligations possible.

In sum, the mark up is a strategic variable that changes both by market influence and decisions made by firms to meet their targets over time. Those targets are established considering the evaluation they make about future prospects of gains, given their perception of the present and future evolution of the macroeconomic context.

## **THE MACROECONOMIC CONTEXT OF INDUSTRIAL FIRMS IN THE 1990s**

Economic reforms in the 1990s can be seen as characterizing an important inflection point in the evolutionary trajectory of Brazilian firms. At least

---

<sup>9</sup> See Fazzari *et al.* (1988) for an empirical exploitation on the links between financial structure and real activity. For an empirical analysis of determinants of private investment in Brazil, see Alves and Luporini (2008).

two main changes can be pointed out as responsible for this inflection: the end of the high inflation regime after the success of the stabilization plan known as the Real Plan, in June 1994, and the commercial and financial deregulation with the end of tariff and non-tariff barriers, which started at the end of the 1980s.

The end of the high inflation regime implied the end of contract indexation, a practice that pervaded all economic transactions. Indexation of contracts was introduced in the mid 1960s as a gradualist strategy to fight inflation. In the early 1980s, when the annual inflation rate reached 3 digits, indexation, both formal and informal, started to become generalized in the economy. Since the indexation system promoted automatic price correction based on past inflation, as it became more diffused, it made the price system downwardly rigid and more sensitive to shocks.<sup>10</sup>

### **Price stabilization**

As mentioned, the 1990s constituted an important inflection point in the evolutionary trajectory of firms in Brazil. In the previous decade, the prevalence of exchange rate protection and of tariff and non-tariff barriers ensured operational profit margins, what did not encourage cost reduction and the introduction of innovations by firms. Moreover, in a highly inflationary context and with widely diffused contract indexation rules, the high level of effective protection allowed firms to informally index their prices on the expected inflation, estimated according to the official exchange rate or the overnight interest rate variation. This defensive behavior by firms aimed at ensuring adequate profit margins and cash flows to preserve their financial capacity toward unexpected cost variations, and to finance investments required to keep their market share. Investment decisions on long term capital formation were strongly discouraged as, under the high inflation regime, time horizon of decisions is shortened. In this sense the

---

<sup>10</sup> For a discussion about the high inflation regime in Brazil, see Feijó and Carvalho (1992). For an extensive investigation about pricing dynamics in the industrial sector in 1960s and 1970s, see Considera (1981), and for the 1980s, see Belluzzo and Almeida (2002, chapter 5).

degree of indebtedness was kept relatively low. On the other hand, the retention of financial assets with contractual indexation clauses played an important role in providing a liquidity buffer which served as a kind of 'insurance' against frequent upheavals in the macroeconomic scenario and economic policies.<sup>11</sup>

A favorable combination of political moment and economic conditions allowed Brazilian government in late 1993 to launch the basis for an economic program that resulted in the end of almost two decades of high inflation. In July 1994 the old currency was replaced by the *real*. The Real Plan was the most successful heterodox stabilization plan, among other stabilization attempts that started in 1986 with the Cruzado Plan. As the other plans, the Real Plan diagnosed that the Brazilian inflation had a strong inertial component. But differently from the others, it did not put in practice price freezing, confiscation of bank deposits and changing in monetary contract rules.

In its conception, the Real Plan followed the traditional method of fighting great inflations of the 20th Century: recovery of trust in the national currency by guaranteeing its external value. The monetary anchor was the stabilization of the rate of exchange through the inflow of external financing and the accumulation of foreign reserves in an amount enough (so it was believed) to discourage speculative attacks against the fixed parity. After so many disappointments in previous stabilization plans, the objective of the economic team responsible for the Real Plan was to implement it gradually, without surprises. So the replacement of the currency was made, in a first stage, substituting the old currency for an indexed currency, daily updated. At the end of June 1994, the new currency was finally launched. The fiscal issue was a concern when formulating the announced plan in late 1993, so at the time of the introduction of the new currency the financial situation of the public sector was comfortable.

---

<sup>11</sup> We thank an anonymous referee for pointing out this remark.

## Opening of the economy

Commercial and financial deregulation were being processed since late 1980s. At the time of the Real Plan was launched, the country had rejoined the international financial market, which allowed for a significant accumulation of international reserves.<sup>12</sup> We can say that the success of the Real Plan in keeping prices under control relied, to a great extent, on the use of the fixed exchange rate as an anchor for domestic prices. Excess of external liquidity, together with high domestic levels of interest rate, caused a strong valuation of the *real*. So, on one hand, the opening of the economy increased competition, what contributed positively to restrict mark ups, and it was an important factor to stop the process of passing on costs pressures to final prices. On the other, the valuation of the *real* aided to keep domestic prices under control.

The monthly inflation rate in Brazil did not return to two digits, except in 1999, when the fixed exchange rate regime was abandoned and a flexible regime was adopted. Despite the consumption bubble in 1995, the exchange rate crises in Mexico in that same year, the Asian crisis in 1997 and the Russian crisis in 1998, economic authorities, through demand contention policies, managed to keep inflation under control until the end of 1998. Therefore, the Real Plan and the opening of the economy knocked down the Brazilian chronic inflation. Just to quote two extreme rates, in 1993, the inflation rate, measured by the general price index (IGP), from Getulio Vargas Foundation, was of around 2.708% per year, and in 2005 it was close to 1.0 per cent.

---

<sup>12</sup> Before the Real Plan, Brazil managed to more than triple foreign reserves. In 1989 they were around US\$9.2 billion, rose to US\$23.7 billion in 1992 and reached US\$32.2 billion in late 1993, when the Real Plan was announced. At the time of the Monetary Reform, the reserves were more than US\$43 billion, a level that corresponded to 18 months of imports and more than enough to sustain the setting of the exchange rate as an instrument of the stabilization policy. Other aspects of the Brazilian foreign sector at the time of the plan were also solid: trade surplus in 1993 was US\$13.3 billion and the current transactions deficit was US\$675.9 million.

## **Financial fragility after stabilization**

Thus, from 1994 onwards the economic environment was one of a low indexation level, a permanent and successful inflation control policy, but with low growth rates. Economic policy showed a stop- and- go pattern, signaling to economic agents that inflationary threats would be fought by strict demand control. The main threats came from the external crisis mentioned above.

Periphery economies, like the Brazilian, had always been more vulnerable to debt crisis, and the globalization process in the 1990s did not diminish this vulnerability. The financial deregulation process of the Brazilian economy involved the promotion of attractive financial assets that could be taken over by international investors –such as public debt securities with short term of maturity and high liquidity, shares of companies under privatization, and so on.

Emerging markets are in general more affected by changes in moods and opinions concerning the sustainability of their respective exchange rate. So, given the intrinsic financial fragility of recently stabilized currencies, it was necessary that assets offered to attract foreign capital produced high capital gains. In this way it was observed that the process of rapid deflation was followed by a slow drop in nominal interest rates. Real interest rates could not be reduced below certain limits established by the spreads demanded by foreign investors to acquire and keep in their portfolio assets denominated in a weak valued currency. This means that the Brazilian stabilization process was intrinsically vulnerable in direct proportion with the dependence on the entrance of foreign resources. In those conditions, the stabilization that was attained was placed under permanent threat of rupturing, and so was perceived by economic agents.

A combination of valued real exchange rate in a context of open economy contributed to the production of permanent current transactions deficits. 1995 is a landmark year for the country's foreign accounts, given the magnitude of the changes that occurred: the US\$10.5 billion trade surplus in 1994 gave place to a US\$3.5 billion deficit and the result of the

current transactions, from a US\$1.8 billion deficit (0.3% of Gross Domestic Product, GDP) increased to US\$18.4 billion (2.5% of GDP). This result occurred in an environment of low growth.

The tendency to produce current account deficits would have required the implementation of structural policies aimed at equalizing the conditions of foreign and domestic competition, besides gradual adjustments to the exchange rate. However, the liberal economic policy followed adopted as its main instrument of control of macroeconomic policy, the interest rate, which was kept at high levels with negative impact on public and external deficits and on investment decisions in fixed capital.

Lastly, the same exchange rate valuation that supported fast deflation, broadened the component that in the formation of the interest rate was correlated with the expectation of exchange rate devaluation. So, to keep credibility on the parity of the exchange rate, the manipulation of the interest rate was the only instrument of monetary policy used every time the *real* underwent a speculative attack. To contain the outflow of capital in the face of foreign crisis, domestic interest rate suffered sharp increases, and this happened in 1995, 1997 and 1998 after the Mexican, the Asian and the Russian crises, respectively. Therefore, it is not surprising that Brazil displayed, after 1994, the highest interest rates among the emerging economies and by global standards –on average, above 20% per annum–. In early 1999 the exchange rate was devalued, and the fixed regime abandoned.

### **Private production and investment decisions in the 1990s**

From the firms' point of view, with the commercial deregulation process, they were induced to focus their activities on becoming more competitive. Privatizations, in turn, opened up opportunities for buying and selling companies which, together with the corporate market dynamism, leveraged the restructuring of firms in the industrial and service sectors. The sensible broadening of domestic markets brought by monetary stabilization and the over valuation of the *real* created favorable conditions for a number of firms to respond to the competitive pressure produced by imports, through

modernization and improving quality of their products. However, as already mentioned, the new more competitive scenario did not stimulate growth.

Modernization implied more imports. So, after a long hibernation period the Brazilian industrial structure underwent a process of renewal/modernization of the basket of products offered, and the massive absorption of organizational and technological improvements known as productive catch up. In this sense, the exchange rate valuation played a dual, contradictory, role of lowering the price of foreign competing products on one hand, and of inputs and capital goods responsible for the productive modernization and diversification of production lines, on the other. It should be remarked that Brazilian industry reacted positively to the new opportunities and challenges. The effects were shown in the industrial productivity growth. Between 1991, before the commercial deregulation, and 1999 labor productivity grew 8.8%.<sup>13</sup> As the level of investment in fixed assets was very low, industrial employment severely decreased.<sup>14</sup> The rate of gross capital formation as a percentage of the GDP was around 17% between 1991 and 1999.

So, despite the punitive macroeconomic environment, the significant growth in productivity, opened space to the drop in production costs. This finding suggests the hypothesis that although the real exchange rate dropped 48.4% between 1985 and 1998,<sup>15</sup> the drop in real prices perceived by the exporting sector was compensated by the reduction in unit costs, which in this way preserved the profit margin/mark up. Perhaps this fact explains why exports grew between 1991 and 1998, leaping from US\$31.6 to US\$51.1 billion in an overvalued exchange rate context.

The exchange rate valuation that occurred after the Real Plan in 1994 had different impacts on price formation among the sectors. Non-tradable goods firms, mainly in the service sector, were in a better position to manage

---

<sup>13</sup> According to the monthly industrial surveys of the Brazilian Statistical Office.

<sup>14</sup> As a consequence, informality rose in labor market.

<sup>15</sup> This result is obtained when the deflators used are the wholesale prices. When consumer price indexes are used, this drop is 67.1 per cent.

the trade off between the desired mark up and preservation of the market share. The same did not happen in tradable goods sector, basically from the manufacturing firms that were exposed to greater foreign competition. The valuation of the exchange rate induced a replacement of local production by imports, mainly those that had abundant international supply of credit at low cost.<sup>16</sup> So, de-industrialization followed the opening of the economy.

The constant threat of a sharp devaluation of the currency added more uncertainty in the macroeconomic context, affecting negatively long run expectations. Overvaluation of the currency discouraged projects aimed at exporting, promoted a shrinking of important chains of production –also affected by predatory imports– and increased foreign property share in the domestic capital stocks.

The impact of high domestic interest rates might also have been different for sectors, depending on the access firms had to the credit market- domestic and international. However, as we have already seen, investment decision in fixed assets were kept low, given in part the uncertainties surrounding the long run prospects of growth of the economy and the high cost of finance. Even firms with access to international capital markets that could take advantage of lower interest rates to finance investment, might have been affected negatively in the formation of their investment expectations by the external vulnerability of the financial accounts of the country.

To sum, financial and commercial deregulation and price stability significantly altered the price formation process in Brazil from mid nineties on. The commitment to maintain operational revenue, current profitability and profit margin, in a context of high uncertainty, given the vulnerability of the economy to foreign crises and high exposition to international competition, required from firms changes in production and pricing strategies, technological restructuring, and very often the acquisition of new assets or the sale of existing ones.

---

<sup>16</sup> In our econometric study reported further on, we found that the real exchange rate had direct influence on the mark up, being the most significant component explaining the determination of the mark up in the period.

Given this macroeconomic scenario in the 1990s, the objective of the next section is to empirically investigate the influence of microeconomic and macroeconomic variables on the industrial firms' determination of the mark up. In this sense, at the macroeconomic level, it is assumed that inflation, interest and exchange rate variables, the level of commercial and financial deregulation and the domestic aggregate demand performance delimited the firms' potential cash-flows. At the microeconomic level, it is assumed that the supply price reflects the firms cost structure and market power. Given these conditioning factors, firms sought to define current mark ups to their direct average costs which, by ensuring their business profitability, generated income flows and profit margins capable of securing their expansion strategies. Hypothetically, such strategies are basically aimed at defining the adequate level of barriers against the new entrants, and ensure an adequate mix of self-financing and external financing for investment funding.

### **DETERMINANTS OF MARK UP IN THE MANUFACTURING INDUSTRY IN THE 1990s**

In the mark up determination model for the Brazilian industry in the 1990s, both macroeconomic and microeconomic variables were considered according to the theoretical arguments developed above. Given the availability of data, the mark ups were constructed for industrial sectors, and not for industrial firms, considering prices and average production costs as references. In this sense, changes in terms of monopoly power and changes in intra-firm cost structure were not captured.<sup>17</sup> We believe that even with such limitation, the exercise undertaken yielded interesting results that are widely consistent with the theoretical discussion presented.

---

<sup>17</sup> As our sample captures large firms, the dispersion of individual mark ups should be low. For a discussion about mark up dispersion, see Roberts and Supina (1997).

## Econometric procedures and data estimates

Our objective is to emphasize economic and intuitive arguments to explain the determination of the mark up in the Brazilian industrial firms in the 1990s. We chose to employ clear and intuitive estimation procedures, however in a very strict sense.

Tests were carried out for the presence of common unit roots to all cross-sections, as well as tests with individual unit root process. In general, the results are inconclusive, but there are series  $I(0)$  and  $I(1)$ . However, the power of these tests is strongly affected by the size of the sample. Preliminary experiments indicated that the series are cointegrated, although this conclusion does not hold in the presence of series with different integration order.

In the estimated models (equations) no evidence was found of nonstationarity in the common and individual idiosyncratic errors, which is coherent with the fact that the panel data have a common factor (Bai and Ng 2004). In face of this argument, it was decided to estimate the model in levels.<sup>18</sup>

The model specification followed the criterion of starting from the more general to the more parsimonious specification following the analysis of common factors. Since the preliminary experiments indicated the presence of a strong serial correlation, the error term has been specified as a first order autoregressive process –AR(1)–. This, however, was not sufficient to eliminate the entire autocorrelation for several models. Also, a dummy for economic policy was included to reduce the size of the outliers present in 1993 and 1999 and, in this way, obtain residuals closer to being Gaussian ones.

The selection criterion of the equations estimated was to choose those which residuals presented none or little serial correlation. This criterion eliminated all specifications with fixed and random effects, as well as equations with variables as first differences. The same procedures were applied to the Stein's Unbiased Risk Estimate (SURE) specifications.

---

<sup>18</sup> The reported analysis is not included in the article but is available for anyone interested.

The models were estimated by Feasible Generalized Least Squares (FGLS) and the coefficient of the variance matrix was estimated with the White robust estimate version corrected by the degrees of freedom, which is designed to accommodate arbitrary serial correlations and time-variant variances of the disturbances.<sup>19</sup>

The panel model is specified as follows:

$$Y_{it} = X_{it}\beta_X + Z_{it}\beta_Z + D_t\delta + u_{it}$$

for  $M$  cross-sectional units ( $i = 1, \dots, M$ ) and  $T$  time periods ( $t = 1, \dots, T$ ) and where

$Y_{it}$ : is the mark up value ( $MU$ )

$X_{it}$ : is the vector of  $k$  explanatory macroeconomic variables

$X_{it}$ : [ $X^1_{it}, X^2_{it}, \dots, X^k_{it}$ ]

$Z_{it}$ : is the vector of  $g$  explanatory microeconomic variables

$Z_{it}$ : [ $Z^1_{it}, Z^2_{it}, \dots, Z^g_{it}$ ]

$D_t$ : is the vector of  $s$  dummy variables

$D_t$ : [ $D^1_t, D^2_t, \dots, D^s_t$ ]

$\beta_X, \beta_Z, \delta$  are vectors of coefficients

---

<sup>19</sup> Although the Generalized Method of Moments (GMM) estimation model is more general than those presented in the paper, estimation dynamic panel data presents many problems. We performed many trials in order to study as many dynamic panel data (DPD) models as possible. Most specifications displayed reasonable diagnostic residuals. However, in all estimated models the coefficients of variables as imports penetration, real interest rate, sector GDP and investment profitability are non-significant and/or have the wrong signs. The relative sector price may be significant or not. In general, only the current and the lagged real exchange rate are significant and have correct (positive) signs. To sum up, the fitted models have no economic meaning because only the exchange rate matters in determining the mark up behavior. Therefore, in spite of being concerned about the simultaneity of the microeconomic variables, like profit margin and investment profitability, we chose to discard DPD/GMM estimation. Furthermore, if we do not employ lagged variables we can catch the long run relationship among the mark up and some intervening variables which shed light on the firm's decision process.

$$\beta_X = \begin{bmatrix} \beta_{X1} \\ \beta_{X2} \\ \vdots \\ \beta_{Xk} \end{bmatrix}, \beta_Z = \begin{bmatrix} \beta_{Z1} \\ \beta_{Z2} \\ \vdots \\ \beta_{Zg} \end{bmatrix}, \delta = \begin{bmatrix} \delta_1 \\ \delta_2 \\ \vdots \\ \delta_s \end{bmatrix}$$

$u_{it}$  is an error term that follows a stationary AR(1) process

$$u_{it} = \rho u_{it-1} + \varepsilon_{it}$$

Where:

$$|\rho| < 1 \text{ (i.e. strictly stationary)}$$

$\varepsilon \approx N(0, \Sigma)$ ,  $\Sigma$  is the variance-covariance matrix of order  $M$ .

We consider the following explanatory variables:

$$X_{it} = [PIBS_{it}, PEN_{it}, IPASR_{it}, Q_{it}, RA_{it}]$$

$$Z_{it} = [ML_{it}, RI_{it}, GA_{it}]$$

Where:

*MU*: mark up, constructed as the quotient of the value of production of one sector by the sum of its respective intermediate consumption, salary and contributions, obtained from the input-output matrix of Brazil from 1985 and 1990 to 1998. For the year of 1999 mark up was estimated using the quotient of the variation of the sector wholesale price index (IPA) –the Brazilian wholesale price index from the Getúlio Vargas Foundation (FGV)– and the sector cost variation index from the Foreign Trade Foundation (Fundação Centro de Estudos do Comercio Exterior, FUNCEX). Table A1 (Appendix) contains the annual mark up estimates for the 26 sectors. The last line and column contain the annual and sector averages and standard deviations, respectively.

*PIBS*: sector GDP; obtained from the National Accounts computed by the Brazilian Statistical Office (Instituto Brasileiro de Geografia e Estatística, IBGE).

*PEN*: imports penetration coefficient, calculated as the quotient of the value of imports by sector and the difference between the sector value of production and its net exports, all estimates obtained from the input-output matrix produced by IBGE.

*IPASR*: relative annual sector producer price index, calculated by dividing the sector IPA by the manufacturing industry index. The monthly indexes were aggregated by the annual average. For the petroleum refinement sector it was constructed an index based on the annual prices of petroleum, computed by the National Agency of Petroleum (Agência Nacional do Petróleo, Gás Natural e Biocombustíveis, ANP).

*Q*: real exchange rate, defined by the value of the dollar in domestic currency times the United States producer price index (PPI), divided by the FGV wholesale price index, both indexes, August 1994=100. The real exchange rate was calculated for the month and aggregated by the annual average.

*RA*: annual real rate of interest; obtained considering the nominal basic rate of interest (SELIC) determined by the Brazilian Central Bank, discounted by the inflation rate obtained through the monthly general price index (IGP-DI) from FGV.

*ML*: profit margin; calculated as net profit/net operational revenue available at *Gazeta Mercantil Annual Balance*.

*RI*: investment profitability, calculated as asset equivalence result/asset balance value from *Gazeta Mercantil Annual Balance*.

*GA*: sector leverage degree, calculated as net debt/net worth from *Gazeta Mercantil Annual Balance* considering the relation.

Finally, it should be added that the primary data used in this paper was obtained from a survey originally developed for Economic Commission for Latin America and Caribbean (ECLAC) (Miranda and Cerqueira 2001). Despite the availability of the mark up series for the period from 1985 to 2000 we chose to analyze in this paper a shorter period (1990-1999) that contained data for all variables of interest (8) and the highest possible number of sectors (26). In this way we built up a database of balanced panel (balanced panel data), containing 243 observations.

## Results

The estimated models (4) are presented in table 1. Table 2 contains reports of residuals diagnostics.<sup>20</sup>

All equations contain an autoregressive term to soften the residual serial correlation. The dummy for economic policy was not introduced in specification 1.<sup>21</sup> In equation [3] the variables are specified in logarithms. In equation [4], the cross-section GDPs were replaced by the annual sector average GDP (*PIBSM*) as it was observed that, due to the lack of data, in several sectors GDP data were repeated.

In table 2 it can be noted that equation [4] presents residuals closer to being Gaussian and independent and identically distributed. Although the self regressive term coefficients are high, they are all statistically smaller than 1. By observing the AR(1) process impulse-response functions –not reported– in all models, they are found to be stable, that is, converge to zero. The equation in logarithms [3] is the one that presents the best stability standard.

The most interesting finding in the econometric exercise is that the sector GDP (*PIBS* and *PIBSM*) presented a negative sign in all 4 selected specifications, suggesting that the mark up behavior showed an anti-cyclical behavior in the period of the study. Considering that mark ups did not show a trend to fall after the opening of the economy (table A1), this can be interpreted as an important indication of the defensive behavior of firms that were exposed to greater uncertainties as the macroeconomic context changed significantly in the 1990s.

---

<sup>20</sup> The reports on the models presented contain the  $R^2$  statistics, standard regression error (*SER*), F statistic  $p$ -value, Durbin-Watson (*DW*) statistic together with its  $p$ -value. The asymmetry coefficient (*sk*) and the excess residuals Kurtosis (*ek*) are also reported. Besides the Ljung-Box statistics  $p$ -values [ $Q(p)$ ] for the second, fourth, sixth and eighth order to test for the presence of serial correlation in the residuals; Bera-Jarque (*BJ*) to test the normality; Goldfeld-Quandt [ $GQ(b)$ ] for the heteroskedasticity; and the Brock, Dechert and Scheinkman's test (*BDS*) test for independence of residuals specified with dimension 6 and distance of 0.7.

<sup>21</sup> As suggested above, the irrelevant variables were deleted from the equations.

Note: \* Q(1) = 0.8726.

Higher uncertainty, in spite of the stabilization of prices from 1994 onwards, might explain why industrial firms in a more competitive scenario and showing significant productive gains did not lower their mark ups, neither did increase their capital accumulation in fixed assets. In a macroeconomic context of slow growth and high uncertainties about the future, given mainly the high degree of external vulnerability of the economy, the rational choice for firms was to use their market power to preserve their market share. In equation 3, for example, a 1% increase in the sector GDP (*PIBS*) induces a drop in the mark up of approximately 0.001 per cent.

Besides this evidence, in all the equations the signs of the relevant variables correspond to the theory forecast. Starting with the macroeconomic variables, we observe that when the real exchange rate variable ( $Q$ ) rose, it increased the domestic protection degree in relation to imports, also implying an increase in the mark up. During a large part of the period analyzed, the exchange rate was overvalued, reducing the domestic production protection degree and therefore the exchange rate contributed to contain the firms' mark up. As already mentioned this variable was the most significant component to explain the determination of the mark up in the period. The variation of the relative price of the sectors (*IPASR*), that is, a variable that theoretically captures the firm pricing power, implied an increase in the mark up.

The rise in the real interest rate ( $RA$ ), raises the cost of loans, stock loading and reduces the aggregate demand and, therefore, tends to reduce sector mark ups. During the 1990s, the real interest was maintained in high levels and the aggregate demand under control most of the time, a fact which also contributed to compress the mark ups.

Taking equation [3], for example, imports penetration degree ( $PEN$ ) has the highest negative impact, that is, a 10% increase in the economy opening degree implies a 3% drop in the sector mark ups. This result confirms the importance of foreign competition through the process of economic opening in containing tradable goods price increases.

Finally, variables that represent microeconomic relations explaining the mark up behavior—profit margin, investment profitability and the degree of

leverage— presented the expected sign. Profit margin directly affects mark up determination (equations [2] and [4]). Investment profitability (equations [2] and [4]) showed a positive effect on the mark up, which indicates that the mark up behavior is related to the investment decision. The degree of leverage ( $GA$ ) presents a negative relation with the mark up, which means that a smaller leverage power pressures the demand to generate internal funds to finance investments. About this evidence we should remark that Pereira and Carvalho (2000:18) observed growing industrial firm leverage levels after monetary stabilization in Brazil. However, according to them, these levels would be relatively low when compared to the average for Asian countries in the 1990s, for example. The observation that there was an increase in the leverage power and that the investment level in fixed assets was relatively low reinforces the anti-cyclical behavior of the mark up, which aimed at preserving firm's market share.

## CONCLUSION

The discussion about the behavior of industrial mark up in Brazil in the 1990s has produced little consensus among authors. We believe that part of the difficulty in dealing with this subject is the lack of a compatible official statistical data for the industrial sector for the decade that limited empirical studies.<sup>22</sup> In this context we believe that the contribution of this paper to the literature has been to bring some empirical evidence about mark up behavior based on a Post Keynesian interpretation.

In order to accomplish our objective we started with a brief presentation of the Post Keynesian pricing theory. According to this approach, the mark up is the strategic variable that firms administrate according to the perception regarding their opportunities of growth. In this perspective price variations depend on decisions about the mark up, and it is the need to accumulate

---

<sup>22</sup> It should be observed that industrial surveys produced by the Brazilian Statistical Office underwent major methodological changes in mid 1990s, compromising comparison along the decade. For a brief discussion about this matter, see Feijó and Carvalho (1999).

internal resources aimed at financing growth that it is understood as the main motivation to the determination of the mark up. In conclusion, there is no automatic mechanism to explain how costs and demand pressures are passed on prices. Post Keynesian pricing theory establishes a complex set of interactions among micro and macroeconomic variables to explain price changes in monetary economies.

With this analytical perspective in mind, we presented the macroeconomic scenario of the Brazilian economy in the 1990s. This scenario was marked by price stabilization and economic opening. A combination of domestic high interest rate, fix exchange rate regime and high uncertainty in the external environment led the economy to a stop-and-go pattern of growth. Opening of the economy and exchange rate overvaluation had a dual contrary effect on pricing decisions of industrial firms: it lowered production and investment costs, but it increased competition. The result was modernization of the productive structure on one side followed by de-industrialization, and price stabilization, on the other. Modernization and the recovery of productivity growth occurred with low levels of investment in fixed capital. So price stability, productivity growth and increased competition did not result in sustained economic growth pushed by an investment boom.

Mark ups did not show a trend to decrease, signaling that firms were able to preserve their profit margins. The question to be answered is why under a more competitive environment and sustained mark ups industrial firms invested little in fixed capital. One suggested possibility is that the 1990s were a period of high macroeconomic uncertainty in the economy. Firms moved from a period of high inflation regime at the beginning of the decade to a price stability period after the Real Plan, which highly relied on exchange rate stability. The second half of the decade was marked by speculative attacks on the currencies of emerging economies, among them the *real*. Sharp increases in domestic interest rates were largely used to refrain capital flight. The dependence on external flow of capital to keep price stability put the economy in a macroeconomic trap: if it grew too fast, balance of payments imbalances threatened exchange rate stability and so aggregate demand was restricted by economic policy. In this scenario,

long term investment plans would be discouraged either by the high cost of finance and/or by expectations of low growth rates. A rational choice for firms would be to follow a defensive strategy, keeping market shares with low investment.

In our empirical analysis we developed an econometric exercise exploiting how micro and macroeconomic variables affected the determination of the mark up in the 1990s. An interesting result is that mark up showed an anti-cyclical pattern. This finding confirms our hypothesis of a defensive behavior by firms. Among the macroeconomic variables, the real exchange rate was the most important to explain the determination of the mark up. Overvaluation of the exchange rate after the Real Plan reduced domestic production protection degree and therefore the exchange rate contributed to contain the firms' mark up. Other macroeconomic variables, as changes in relative price, real interest rate and imports penetration showed the expected signal. Microeconomic variables confirmed the Post Keynesian hypothesis that the mark up is influenced by variables related to investment decision in fixed capital such as profit margin, investment profitability and degree of leverage.
